- Summary

NEUTRINO ELECTRON INTERACTION

WEAK INTERACTION

Figure: Neutrino-electron interaction

Effective Lagrangian

$$\mathcal{L}_{\text{eff}} = -\frac{G_F}{\sqrt{2}} \left\{ [\bar{\nu}_e \gamma^\rho (1 - \gamma^5) e] [\bar{e} \gamma_\rho (1 - \gamma^5) \nu_e] \right. \\ \left. + [\bar{\nu}_e \gamma^\rho (1 - \gamma^5) \nu_e] [\bar{e} \gamma_\rho (g_V^l - g_A^l \gamma^5) e] \right\}$$

- Red: charged current which exchanges the charge;
- Blue: neutral current

In the context of weak interaction, for a Lagrangian,

$$\mathcal{L}(\psi_1, \psi_2, \psi_3, \psi_4) = [\bar{\psi}_1 \gamma^\mu (1 - \gamma^5) \psi_2] [\bar{\psi}_3 \gamma_\mu (1 - \gamma^5) \psi_4],$$

exchange the field ψ_2 and ψ_4 doesn't change the result.

The Lagrangian is called V-A theory because people define

$$\mathcal{L}^V(\psi_1, \psi_2, \psi_3, \psi_4) = [\bar{\psi}_1 \gamma^\mu \psi_2] [\bar{\psi}_3 \gamma_\mu \psi_4],$$

$$\mathcal{L}^A(\psi_1, \psi_2, \psi_3, \psi_4) = [\bar{\psi}_1 \gamma^\mu \gamma^5 \psi_2] [\bar{\psi}_3 \gamma_\mu \gamma^5 \psi_4].$$

Fierz Transformed Lagrangian

$$\mathcal{L}_{\text{eff}} = -\frac{G_F}{\sqrt{2}} \{ [\bar{\nu}_e \gamma^\rho (1 - \gamma^5) e] [\bar{e} \gamma_\rho (1 - \gamma^5) \nu_e] \\ + [\bar{\nu}_e \gamma^\rho (1 - \gamma^5) \nu_e] [\bar{e} \gamma_\rho (g_V^l - g_A^l \gamma^5) e] \}$$

is transformed to

$$\mathcal{L}_{\text{eff}} = -\frac{G_F}{\sqrt{2}} [\bar{\nu}_e \gamma^\rho (1 - \gamma^5) \nu_e] [\bar{e} \gamma_\rho ((1 + g_V^l) - (1 + g_A^l) \gamma^5) e]$$

What's Good about This New Lagrangian

$$\mathcal{L}_{\text{eff}} = -\frac{G_F}{\sqrt{2}} [\bar{\nu}_e \gamma^\rho (1 - \gamma^5) \nu_e] [\bar{e} \gamma_\rho ((1 + g_V^l) - (1 + g_A^l) \gamma^5) e]$$

The neutral current only processes $\nu_{\mu,\tau} e^- \rightarrow \nu_{\mu,\tau} e^-$ are similar to this

$$\mathcal{L}_{\text{eff},\mu\tau} = -\frac{G_F}{\sqrt{2}} [\bar{\nu}_e \gamma^\rho (1 - \gamma^5) \nu_e] [\bar{e} \gamma_\rho (g_V^l - g_A^l \gamma^5) e]$$

We calculate the $\nu_e e^- \rightarrow \nu_e e^-$ processes only.

SPIN DEPENDENT INTERACTION

Current

Current is

$$\vec{J} = 2\rho \frac{\vec{v}}{\sqrt{1-v^2}},$$

where v is the velocity of electrons with respect to the CNB.

Interaction Energy

The interaction energies for two different helicity states are,

$$\frac{G_F}{\sqrt{2}} \vec{\sigma} \cdot \vec{J} = \pm \sqrt{2} G_F \rho \frac{v}{\sqrt{1-v^2}}.$$

Number Density

$$\rho \propto p_F^3.$$

Energy Split and Frequency

$$\Delta E = 2\sqrt{2}G_F\rho\frac{\vec{v}}{\sqrt{1-v^2}} = 0.6 \times 10^{-24} \left(\frac{p_F}{\text{eV}}\right)^3 \frac{v}{\sqrt{1-v^2}} \text{eV}$$

What is Fermi Momentum p_F

- β decay: $p_F \leq 60\text{eV}$
- cosmological: $p_F \leq 0.75 \times 10^{-2}\text{eV}$

Energy Split

Energy split is of the order

$$\Delta E \sim 10^{-19} \text{eV to } 10^{-30} \text{eV}$$

Energy split tells us the frequency.

POSSIBLE DETECTION METHODS

Electron Beams

- Electron Beams with equally \pm helicity states.
- + and - states have different energies = two different frequencies.
- Phase difference between the two states.

How Large is the Phase Difference

$$\begin{aligned}\phi &\sim \Delta E t \sim 2\sqrt{2}G_F\rho z \\ &\sim 3 \times 10^{-20} \left(\frac{p_F}{\text{eV}}\right)^3 \text{ rad/cm}\end{aligned}$$

For one light year, we gain a phase difference of the order $\left(\frac{p_F}{\text{eV}}\right)^3$ rad.

Ferromagnetic Material

- A big chunk of ferromagnetic material (1 ton) contains 10^{27} aligned electrons.
- Torque of order $\left(\frac{p_F}{eV}\right)^3 \text{ eV}$

Problems

- a small torque
- external B field

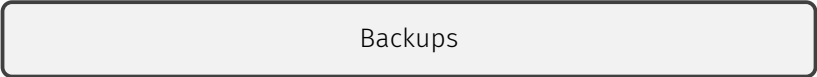

Neutrons

The estimation also works for neutral current only processes. He^3 mixed into low temperature He^4 can retain the spin for a long time. Thus we could use the spin dependent interaction of nuclei to detect CNB.

Methods

- Electrons of equally mixing helicity states : a small phase difference
- 1 ton of ferromagnetic material : a small torque
- He^3 nuclei : phase difference similar to electrons

Backups

SR Velocity Transformation

$$u' = \frac{u - v}{\sqrt{1 - v^2}}$$

Current

$$\vec{J} = -\frac{i}{2m} (\Phi^* \nabla \Phi - \Phi \nabla \Phi^*)$$

Magnetic Moment and B Field

$$\Delta E = -\vec{\mu} \cdot \vec{B}$$
